

Hypergenes node tree

Hypergenes node tree is a large part of the Hypergene product. The tree consists of so called nodes that can be children and/or parent. A node that isn't a parent is called a leaf.

Hypergenes node tree

Nodes can be parents

Nodes can be children

Nodes that don't have any children are called leaves.

Nodes can have several parents. In the example above node 2 has two parents.

Worth noting is that node 2 is still the same node even though you can see it twice in the node tree. This means that if we were to delete node 5 from one of the places in the node tree it would disappear from all places.

Common sense in the node tree – deleting nodes

If you have to make changes in the node tree it is important to be careful.

If we want to delete a node that has children, we have to move or delete the children first (to avoid orphans in the node tree).

To delete node 2, we first have to delete node 5 and node 6. When we have deleted them, we can delete node 2.

Generally, we try to avoid deleting nodes in the node tree (because there might be data/facts connected to them). A way of removing the nodes from a structure could be to drag to another parent.

The first step is to move node 2 to the parent "not in use". Note that node 2 now has two parents.

The next step is to "unlink" node 2 from node 1.
